6	3 Multi Patch Model Description	5
7	4 Treatment Strategies For Cholera	7
8	5 Comparing Treatment Strategies For Cholera	8

# 1 Introduction

It's time for a theory of everything. Since we're all really smart, we've created one.

## 2 Single Patch Model Description

$$\begin{aligned}\frac{dS}{dt} &= \mu N - \mu S - \beta_i SI - \beta_w SW \\ \frac{dI}{dt} &= \beta_i SI + \beta_w SW - I(\gamma + \mu + \alpha) \\ \frac{dR}{dt} &= \gamma I - \mu R \\ \frac{dW}{dt} &= \xi I - \sigma W\end{aligned}$$

- $\mu$  = natural death rate
- $\beta_i$  = transmission rate between S and I class
- $\beta_w$  = transmission rate between I and W class
- $\gamma$  = recovery rate (I to R class)
- $\alpha$  = death rate from cholera
- $\xi$  = Shedding rate of cholera from I to W class
- $\sigma$  = Removal rate of cholera from W class (depends on what we define as our water source)
- This model assumes that you start off with low intensity symptoms (lower rate of shedding) and the symptoms reach a high intensity with a greater rate of shedding.
- $\alpha_i$  = death rate by cholera in low or high intensity
- $\delta$  = rate at which symptoms increase in severity

Figure 1: Plot of the SIRW model for a single patch. Parameters are  $\mu = 0.15$   $\beta_i = 0.06$   $\gamma = 0.14$   $\sigma = 0.07$   $\beta_w = 0.15$ . Further the initial conditions for the model were  $S_0 = 0.92$   $I_0 = 0.08$   $R_0 = 0$

The basic reproductive number  $\mathcal{R}_0$  is defined as the number of secondary infections as a result of introducing a single infected individual into a completely susceptible population.  $\mathcal{R}_0$  can be computed from the next generation matrix approach, where we write the second generation matrix at the disease free equilibrium as  $FV^{-1}$ , where the  $ij$  entry of the matrix  $F$  is the rate at which infected individuals in compartment  $j$  produce new infections in compartment  $i$ , and the  $jk$  entry of  $V^{-1}$  is the average duration of stay in compartment  $j$  starting from compartment  $k$ . For our model, we have

$$F = \begin{pmatrix} \beta_i & \beta_w \\ 0 & 0 \end{pmatrix}$$

$$V = \begin{pmatrix} \frac{1}{\gamma + \mu + \alpha} & 0 \\ \frac{1}{\gamma + \mu + \alpha} & \frac{1}{\theta} \end{pmatrix}$$

The basic reproductive number is computed as the spectral radius of  $FV^{-1}$  as seen in Tien and Earn (2010), which is

$$\mathcal{R}_0 = \rho(FV^{-1})$$

$$= \frac{\beta_i + \beta_w}{\gamma + \mu}$$

24 This single patch model has a disease-free equilibrium at  $(S, I, W) = (1, 0, 0)$ . It also has an  
25 endemic-equilibrium for  $\mathcal{R}_0 > 1$

$$\frac{dS}{dt} = \mu N - \mu S - \beta_L S I_L - \beta_H S I_H - \beta_w S W$$

$$\frac{dI_L}{dt} = \beta_i S (I_L + I_H) + \beta_w S W - I_L (\mu + \delta + \alpha_L)$$

$$\frac{dI_H}{dt} = \delta I_L - I_H (\gamma + \mu + \alpha_H)$$

$$\frac{dR}{dt} = \gamma I_H - \mu R$$

$$\frac{dW}{dt} = \xi_L I_L + \xi_H I_H - \sigma W$$

- 26 • This model assumes that you start off with low intensity symptoms (lower rate of  
27 shedding) and the symptoms reach a high intensity with a greater rate of shedding.
- 28 •  $\alpha_i$  = death rate by cholera in low or high intensity
- 29 •  $\delta$  = rate at which symptoms increase in severity

### 30 **3 Multi Patch Model Description**

31 more text

Figure 2: Plot of the SIRW model for all patches in a multi patch model. Parameters are  $\mu = 0.15$   $\beta_i = 0.06$   $\gamma = 0.14$   $\sigma = 0.07$   $\beta_w = 0.15$ . The initial conditions for the model were  $S_0 = 0.97$   $I_0 = 0.03$   $R_0 = 0$ . The influence of neighbouring patches is 0.15.

## 4 Treatment Strategies For Cholera

### Treatment Plan 1: Sanitation of water over time

$$\begin{aligned}\frac{dS}{dt} &= \mu N - \mu S - \beta_i SI - \beta_w SW \\ \frac{dI}{dt} &= \beta_i SI + \beta_w SW - I(\gamma + \mu + \alpha) \\ \frac{dR}{dt} &= \gamma I - \mu R \\ \frac{dW}{dt} &= \xi I - \sigma W - \rho(I)W\end{aligned}$$

$$\bullet \rho(I) = \begin{cases} \lambda & I \geq 0.1 \\ 0 & 0 \leq I \leq 0.1 \end{cases}$$

Represents the sanitation (increased removal of cholera) rate of  $\lambda$ , implemented at certain threshold of infected (in this case the threshold is based on I but can be based on W (i.e. testing water levels for cholera))

### Treatment Plan 2: Vaccinations on Base Model

$$\begin{aligned}\frac{dS}{dt} &= \mu N - \mu S - \beta_i SI - \beta_w SW - \nu S \\ \frac{dI}{dt} &= \beta_i SI + \beta_w SW - I(\gamma + \mu + \alpha) \\ \frac{dR}{dt} &= \gamma I - \mu R + \nu S \\ \frac{dW}{dt} &= \xi I - \sigma W\end{aligned}$$

$\bullet \nu$  = is vaccination rate on S class

### Treatment Plan 3: Antibiotics on Base Model

$$\begin{aligned}\frac{dS}{dt} &= \mu N - \mu S - \beta_i SI - \beta_w SW \\ \frac{dI}{dt} &= \beta_i SI + \beta_w SW - I(\gamma + \eta + \mu + \alpha) \\ \frac{dR}{dt} &= (\gamma + \eta)I - \mu R \\ \frac{dW}{dt} &= \xi I - \sigma W\end{aligned}$$

$\bullet \eta$  = is antibiotic rate on I class
